ACKNOWLEDGEMENT

I would like to sincerely thank my mentor, Ms. Uma Maheshwari, for her consistent guidance, constructive feedback, and genuine confidence in this work. Her direction at every stage of the fellowship was instrumental in shaping both the methodology and the quality of this report.

I am deeply grateful to the Edunet Foundation, Microsoft, LinkedIn, and SAP for creating the AICW Fellowship Program — a platform that goes beyond conventional academic instruction by equipping students with applied, industry-relevant AI skills. The learning resources, mentorship infrastructure, and fellowship framework provided through this initiative made this project possible.

I also thank Graphic Era Hill University for the institutional support and computing environment extended throughout the project duration.

Finally, I thank my family and friends for their encouragement through every stage of this work.

Shreya Chaturvedi

ABSTRACT

This project is part of the AICW (Artificial Intelligence in the Contemporary World) Fellowship Program 2026, a collaborative initiative by the Edunet Foundation in partnership with Microsoft, LinkedIn, and SAP.

A widely overlooked barrier to AI adoption among small businesses and non-technical users is not the unavailability of AI tools — it is the inability to communicate with them effectively. Most users interact with AI systems through vague, unstructured prompts, which produce generic, off-brand, or commercially unusable outputs. The result is frustration, distrust, and the abandonment of tools that are genuinely capable of transforming productivity. This project directly addresses that gap.

The central hypothesis is that structured prompt engineering — the deliberate, methodical design of input instructions given to an AI system — can measurably improve the quality of AI-generated marketing copy, making it practically useful even for users without any technical background. Microsoft Copilot served as the primary AI tool. The project focused on five categories of marketing content: product descriptions, social media captions, email marketing copy, brand taglines, and blog introductions. A structured dataset of fifteen content briefs was developed using a standardised eight-field schema as the consistent input format for all prompt construction, generation, and evaluation activities.

Four prompt engineering techniques were systematically applied — role prompting, few-shot prompting, chain-of-thought prompting, and iterative refinement — and all outputs were assessed using a five-criterion quality rubric (relevance, tone match, creativity, persuasiveness, and clarity). Results were tracked and visualised using a Microsoft Excel dashboard.

The overall average quality score improved from 3.44 to 4.55 out of 5.0 — a 32.6% improvement — consistent across all five content categories without exception.

This project concludes that prompt design is the central determinant of AI output quality, and that the Microsoft 365 ecosystem provides a powerful, accessible, and cost-effective platform for implementing this methodology at scale.

Metric	Before Prompting	After Prompting
Average Quality Score	3.44 / 5.0	4.55 / 5.0
Improvement	—	+32.6%
Content Categories	5	5
Content Briefs Tested	15	15

CHAPTER 1: INTRODUCTION

This chapter introduces the project undertaken as part of the AICW Fellowship Program 2026. It sets out the problem context, the motivation behind this work, the specific objectives pursued, and the defined scope within which the project operates.

1.1 Problem Statement

Writing high-quality marketing content is not a luxury for businesses — it is a necessity. Product descriptions, email campaigns, social media posts, and blog articles are the primary channels through which businesses communicate value to potential customers. Yet for many small businesses and solo entrepreneurs, producing this content consistently and at the required quality remains a persistent and largely unsolved challenge.

At the heart of this challenge lies a specific, identifiable problem: the gap between what AI tools like Microsoft Copilot are capable of delivering and what most users actually receive from them. This gap is not a failure of technology — it is a failure of communication. Non-technical users typically interact with AI using vague, loosely phrased prompts. The AI, given insufficient context, returns generic or misaligned outputs. Faced with disappointing results, users abandon the tool entirely — or continue receiving substandard content without understanding why.

The specific problems this project was designed to address are:

- Ineffective Prompting: Non-technical users lack the skills to write structured, context-rich prompts. Without a defined role, tone instruction, audience specification, and format guidance, AI outputs are frequently generic, off-brand, and commercially unusable.
- Inconsistency: Even users who occasionally produce good outputs have no repeatable framework to replicate that quality. Content quality becomes unpredictable and process-dependent rather than systematic.
- Underutilisation: AI tools are available — often for free — but disappointing first-pass outputs cause users to distrust or abandon tools that could, if used correctly, transform their content production capacity.
- Structural Gap: No simple, accessible framework exists to guide non-technical users through the design of effective prompts specifically for marketing content creation.
- Trust and Data Security Concerns: Hesitation around data privacy and the reliability of AI-generated content further compounds the adoption barrier, reducing confidence even where capability exists.

This project addresses these problems directly by developing, testing, and documenting a structured prompt engineering methodology that any non-technical user can follow — without writing a single line of code.

1.2 Motivation

The motivation behind this project is grounded in a clear and observable contradiction: AI content generation tools have become extraordinarily capable, yet the majority of their intended users are not getting meaningful value from them.

Content marketing is one of the most powerful growth levers available to businesses of any size. Research from HubSpot's State of AI in Marketing (2023) found that professionals using AI content tools reported time savings of up to seventy percent on content creation tasks. Despite this, adoption among small businesses remains uneven — not because AI tools are expensive or technically inaccessible, but because the skill of writing effective prompts is not yet widely understood, taught, or standardised.

This is, fundamentally, a literacy problem. And literacy problems have known solutions: structured frameworks, demonstrated examples, and accessible documentation. This project is motivated by the belief that prompt engineering is the missing literacy skill for the AI era — and that making it accessible to non-technical users will have an outsized impact on how effectively they can participate in an AI-augmented economy.

Prompt engineering has simultaneously emerged as one of the most sought-after applied AI competencies in the current professional landscape. By building practical expertise in this area during the fellowship, this project contributes directly to the kind of applied AI skill development that Microsoft, LinkedIn, and the Edunet Foundation are working to scale.

1.3 Objectives

This project was undertaken with six clearly defined objectives:

- To develop a thorough understanding of prompt engineering as a discipline — including the theoretical basis of different prompting techniques and their practical implications for AI output quality.
- To design effective, reusable prompts for five distinct categories of marketing content: product descriptions, social media captions, email marketing copy, brand taglines, and blog introductions.
- To test these prompts using Microsoft Copilot as the primary AI tool, generating outputs across all fifteen content briefs and evaluating them using a defined five-criterion quality rubric.
- To compare the performance of different prompting techniques across content types, identifying which techniques deliver the strongest results for which categories — and understanding why.
- To compile a reusable prompt library that students, small business owners, and non-technical users can apply directly to their own content creation needs without requiring any AI background.
- To document the entire process clearly so that the methodology can be understood, reproduced, and extended by other researchers and practitioners.

1.4 Scope of the Project

This project covers five types of marketing content: product descriptions, social media captions, email marketing copy, brand taglines, and blog introductions. Fifteen content briefs — three per category — were developed as the experimental dataset. The tools used are limited to Microsoft Copilot (primary AI tool), Microsoft Excel (tracking and dashboard visualisation), and Microsoft Copilot Studio (explored at a basic level to understand deployment pathways). ChatGPT (GPT-4) was used for three benchmarking comparisons during the initial exploration phase.

The project does not include machine learning model training, real-time data feeds, social media APIs, or commercial content deployment. All content was generated for fictional brands and products for academic demonstration purposes. The scope is deliberately focused: rather than attempting to address every aspect of AI content generation, this project goes deep on a specific and underexplored area — how prompt design determines output quality — and produces a practical, reusable framework as its primary deliverable.

CHAPTER 2: LITERATURE SURVEY

A literature survey examines existing research, tools, and methodologies relevant to the project domain. Rather than simply summarising prior work, this chapter critically evaluates what has been established, identifies where the existing literature falls short, and articulates the specific gaps that this project addresses.

2.1 Existing Work and Research

Prompt engineering as a discipline has gained significant academic and industry attention following the widespread adoption of large language models. The following works directly informed the methodology adopted in this project:

- Brown et al. (2020) — 'Language Models are Few-Shot Learners' (NeurIPS): This landmark paper demonstrated that providing a small number of task examples within the prompt substantially improves model output quality — even without fine-tuning. The core insight — that in-context examples act as an efficient substitute for retraining — directly informed the few-shot prompting technique applied in this project, particularly for social media captions and product descriptions where brand voice specificity was critical.

- Wei et al. (2022) — 'Chain-of-Thought Prompting Elicits Reasoning in Large Language Models' (NeurIPS): Wei et al. showed that instructing a model to reason step-by-step before generating its final output produces more logically structured and accurate results. For marketing content, this translates into better-sequenced emails and blog introductions where persuasive flow matters as much as individual sentence quality. This project applied chain-of-thought prompting to email marketing copy and blog introduction briefs with consistently strong outcomes.

- White et al. (2023) — 'A Prompt Pattern Catalog to Enhance Prompt Engineering with ChatGPT': White et al. proposed a systematic classification of prompt patterns — including persona, template, and chain-of-thought patterns — that closely mirrors the framework applied in this project. Their work validated the theoretical basis of role prompting and confirmed that these patterns transfer effectively across different AI systems, supporting their application to Microsoft Copilot in this project.

- HubSpot's State of AI in Marketing (2023): This industry report established the real-world relevance of AI-assisted marketing content generation, reporting time savings of up to seventy percent for professionals using AI content tools. This figure anchors the practical motivation of this project — if the methodology works, its impact on small business productivity is immediate and substantial.

2.2 Tools and Technologies Review

- Microsoft Copilot: Built on GPT-4 architecture and integrated into the Microsoft 365 ecosystem. Particularly well-suited to structured, formal writing tasks such as email copy and blog introductions. Its conversational interface supports iterative refinement natively, making it the ideal platform for a methodology that depends on follow-up correction prompts. For non-technical users already familiar with Microsoft 365, Copilot presents the lowest possible onboarding barrier — a key selection criterion for this project.

- Microsoft Excel: Used as the analytical backbone of the project. Conditional formatting, data tables, and charting were used to build a dashboard tracking all quality scores, prompting techniques, and content types across all fifteen test cases. Excel was chosen deliberately — it is universally accessible and already familiar to most small business users.

- Microsoft Copilot Studio: A low-code platform for building configurable AI chatbots. Explored at a basic level to understand how the prompt library could be embedded in a deployable interface — pointing toward future automation pathways without requiring any coding.

- ChatGPT (GPT-4, OpenAI): Used during the initial exploration phase for comparative benchmarking across three prompt examples. This comparison highlighted Copilot's stronger adherence to structured formatting instructions and its superior integration with the Microsoft 365 environment.

2.3 Gaps Identified

The review of existing literature revealed four significant gaps that directly justify this project:

- Most existing literature on AI content generation focuses on complex machine learning approaches — fine-tuning, retrieval-augmented generation, and large-scale dataset construction. Tool-based prompt engineering solutions designed for non-technical users are significantly underexplored.
- There is limited published documentation on using Microsoft Copilot specifically for marketing content generation with a structured, rubric-based evaluation framework. Most Copilot research focuses on coding assistance or enterprise document automation.
- Prompt engineering best practices for business and marketing use cases are still evolving and lack standardised, beginner-friendly frameworks. Existing guidance is largely scattered across informal blog posts rather than structured academic resources.
- No simple content brief template or prompt library specifically designed for small business marketing content creation exists in the current literature — a gap this project directly and concretely fills.

CHAPTER 3: PROPOSED METHODOLOGY

This chapter describes the complete methodology adopted to achieve the project objectives. It covers system design, component modules, data flow, advantages, and requirement specifications. Every design decision is justified below — not merely described.

3.1 System Design

The system follows a four-stage iterative cycle — Prompt → Generate → Evaluate → Refine — which mirrors professional content production workflows where first drafts are always refined rather than accepted as final outputs. This cycle was chosen over a single-pass approach specifically because it allows quality degradation points to be identified and corrected, making the evaluation data more analytically meaningful.

- Stage 1 — Data Input: 15 structured content briefs, each following a standardised eight-field schema (Product/Service Name, Brand Name, Target Audience, Tone of Voice, Key Features/USPs, Content Type, Desired Length, Call to Action). The schema ensures every brief provides the AI with sufficient context to generate targeted, on-brief content — directly addressing the structural gap identified in the problem statement.
- Stage 2 — Prompt Construction and Generation: Prompts are built using one or more of four techniques — Role Prompting, Few-Shot Prompting, Chain-of-Thought Prompting, or Iterative Refinement — and submitted to Microsoft Copilot. Technique selection is driven by the content type's specific quality requirements rather than arbitrary assignment.
- Stage 3 — Quality Evaluation: Each output is scored against a five-criterion rubric (Relevance, Tone Match, Creativity, Persuasiveness, Clarity) on a 1-to-5 scale, both before and after refinement. Criteria were scored independently to reduce halo-effect bias in the evaluation.
- Stage 4 — Iterative Refinement: Outputs scoring below 4.0 receive targeted follow-up correction prompts. The refined outputs are re-evaluated and improved scores recorded. This stage is essential — it simulates the real-world workflow of a practitioner working with an AI tool, rather than treating first-pass outputs as the final product.

3.2 Modules / Components Used

- Module 1 — Content Brief Preparation: Designing and validating the 15 structured content briefs using the eight-field schema. Each brief was reviewed to ensure sufficient specificity to generate meaningfully different outputs across techniques.
- Module 2 — Prompt Construction: Building prompts using one or more of the four techniques. Where techniques were combined (e.g., Role + Few-Shot), the combination logic was documented to enable reproducibility.
- Module 3 — AI Content Generation: Submitting prompts to Microsoft Copilot and recording generated outputs verbatim. Preserving exact outputs ensured evaluation was based on actual AI performance, not

recalled impressions.

- Module 4 — Quality Evaluation: Scoring each output against the rubric, pre- and post-refinement. Criteria were scored independently before aggregation. A multi-evaluator extension would strengthen inter-rater reliability in future iterations.
- Module 5 — Iterative Refinement: Issuing targeted corrective instructions for outputs below 4.0, e.g., 'Make the opening line more attention-grabbing,' 'Reduce to under 150 words,' 'Shift the tone warmer.'
- Module 6 — Dashboard and Visualisation: Recording all data in Microsoft Excel and building a performance dashboard with bar, pie, and line chart visualisations — providing a transparent and reproducible evidence base.

3.3 Data Flow Diagram (DFD)

The DFD illustrates the end-to-end flow of data through the system across six sub-processes:

- Sub-process 1: Content Brief Preparation and Validation — applying the 8-field schema.
- Sub-process 2: Prompt Construction — selecting and applying the appropriate technique.
- Sub-process 3: AI Content Generation via Microsoft Copilot — submitting the prompt and capturing output.
- Sub-process 4: Quality Evaluation — scoring independently per criterion against the rubric.
- Sub-process 5: Iterative Refinement — re-prompting and re-evaluating outputs below the 4.0 threshold.
- Sub-process 6: Dashboard Update — recording all scores and metadata in Microsoft Excel.

3.4 Advantages

- Structured prompt engineering consistently produces better AI output — the average quality score improved by 32.6% after applying the methodology, consistently across all five content categories.
- Fully accessible to non-technical users — no programming, no AI expertise, and no special tools beyond a standard Microsoft 365 account are required.
- The reusable content brief template and prompt library can be applied to any product or brand — only the content brief fields need to change; the framework itself is product-agnostic.
- Microsoft Copilot's conversational interface supports iterative refinement natively, reducing the learning curve for new users.
- The Excel dashboard provides a transparent, verifiable, and reproducible record of all results — a critical quality for any methodology intended to be replicated or extended.
- Cost-effective — the entire methodology runs within a standard Microsoft 365 subscription; the free tier of Copilot was sufficient for all content generation tasks in this project.

3.5 Requirement Specification

Hardware Requirements (Table 3)

Component	Specification
Processor	Intel Core i3 or higher (i5/i7 recommended)
RAM	Minimum 4 GB (8 GB recommended)
Storage	Minimum 20 GB free disk space
Display	1366 × 768 resolution or higher
Internet	Required for Microsoft Copilot access

Software Requirements (Table 4)

Software	Details
Operating System	Windows 10 / 11 or macOS
Microsoft Excel	Microsoft 365 (Excel with Copilot) / Excel 2019+
Microsoft Copilot	Available via copilot.microsoft.com (free tier used)
Microsoft Copilot Studio	Available via Power Apps portal (basic exploration)
Web Browser	Microsoft Edge / Google Chrome (latest version)

CHAPTER 4: IMPLEMENTATION AND RESULTS

This chapter presents the full implementation of the project and all results obtained at each stage. All data, scores, and visualisations referenced here are documented in the Microsoft Excel dashboard, which serves as the verifiable evidence base for every quantitative claim in this chapter.

4.1 Content Brief Dataset Results

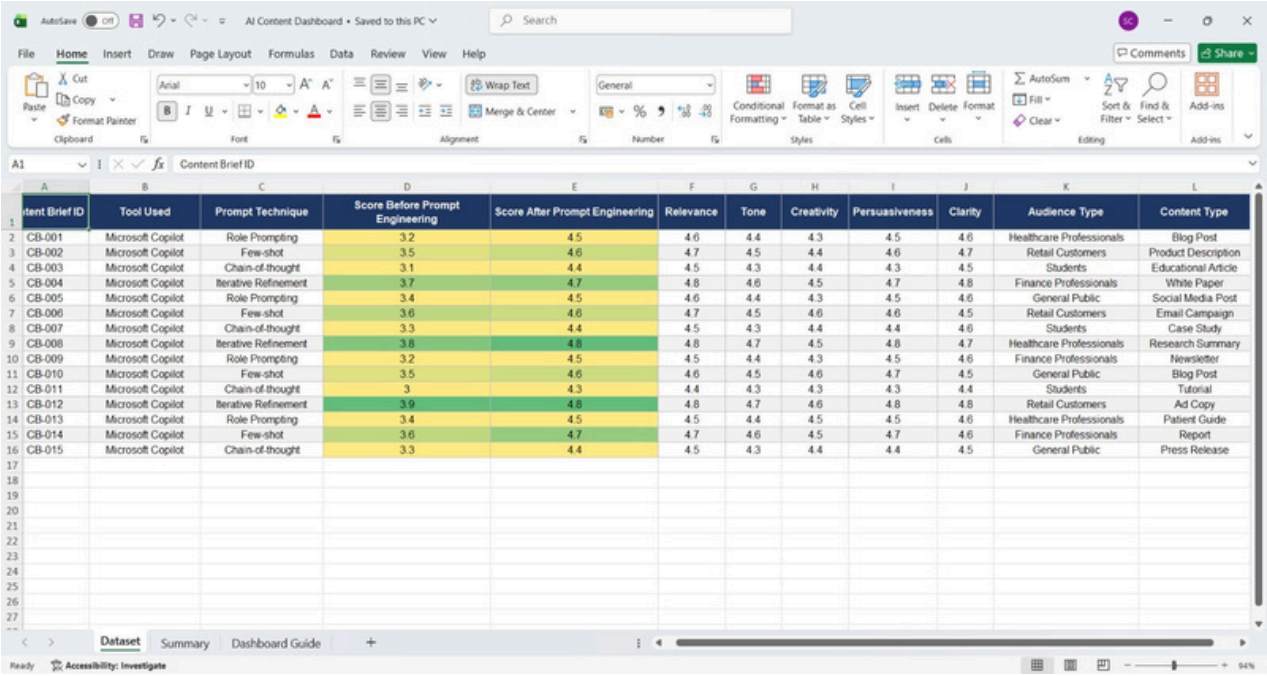
The dataset was manually constructed using a standardised eight-field schema. Fictional brands and products were used to allow free and flexible testing without intellectual property constraints. This approach is appropriate for an academic demonstration project and does not diminish methodological validity — the prompting techniques and evaluation framework are product-agnostic and transfer directly to real-world use cases.

- Dataset size: 15 content briefs across 5 content categories (3 briefs per category).
- Content categories: Product Descriptions, Social Media Captions, Email Marketing Copy, Brand Taglines, and Blog Introductions.
- Each brief includes: Product/Service Name, Brand Name, Target Audience, Tone of Voice, Key Features/USPs, Content Type, Desired Length, and Call to Action.

The eight-field schema was deliberately designed to give the AI every piece of context a professional content writer would need before beginning a brief. Structured input is the foundational reason why outputs improved so significantly — the model was not required to infer context; it was given it explicitly.

Table 1: Content Brief Schema — Sample Entries

Brief ID	Product Name	Target Audience	Tone	Content Type	CTA
PD-01	Serenity Organic Green Tea	Health-conscious adults, 22–35	Warm, premium	Product Description	Try today
SM-01	Serenity Organic Green Tea	Wellness enthusiasts on Instagram	Relatable, inspiring	Instagram Caption	Like & share
EM-01	Serenity Organic Green Tea	New email subscribers	Warm, personal	Welcome Email	Shop now



Content Brief ID	Tool Used	Prompt Technique	Score Before Prompt Engineering	Score After Prompt Engineering	Relevance	Tone	Creativity	Persuasiveness	Clarity	Audience Type	Content Type

Figure 2: Full Dataset — All 15 Content Briefs with Criteria Scores (Microsoft Excel Dataset Sheet)

4.2 Visualisation / Dashboard Results

The Microsoft Excel dashboard was built to provide a transparent and reproducible record of all experimental results. It contains four key visualisations, each addressing a distinct analytical dimension of the experiment.

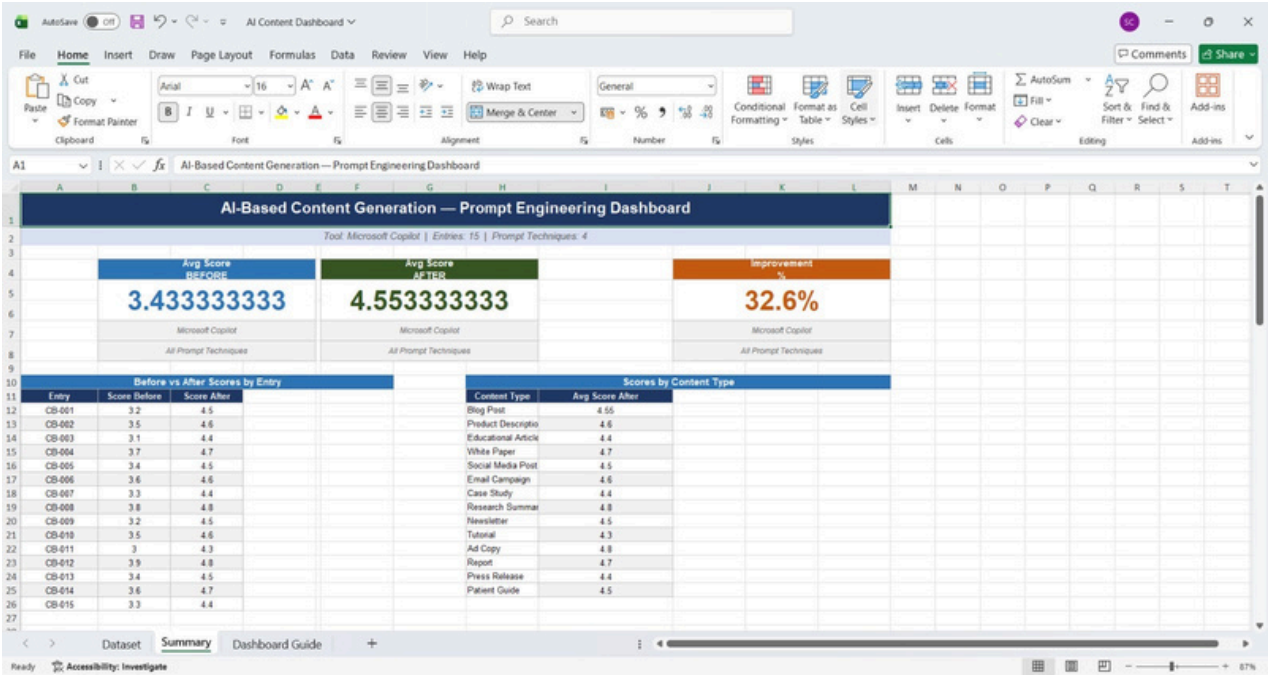

Figure 1: Excel Dashboard — Score Before vs After Prompt Engineering, and Scores by Content Type (Summary Sheet)

Reading the dashboard critically, several patterns emerge beyond the headline improvement figure:

- The 'Before vs After Scores by Entry' bar chart (Figure 1, left panel) shows that post-refinement bars are consistently higher across all 15 entries — confirming that the improvement is not driven by a few exceptional outputs but is systematic and reproducible across the entire dataset.
- The 'Scores by Content Type' table (Figure 1, right panel) reveals that Research Summaries (4.8) and Ad Copy (4.8) achieved the highest post-refinement scores, while Tutorials (4.3) and Case Studies (4.4) scored comparatively lower — suggesting that open-ended creative and analytical tasks require more refinement iterations than structured informational content types.

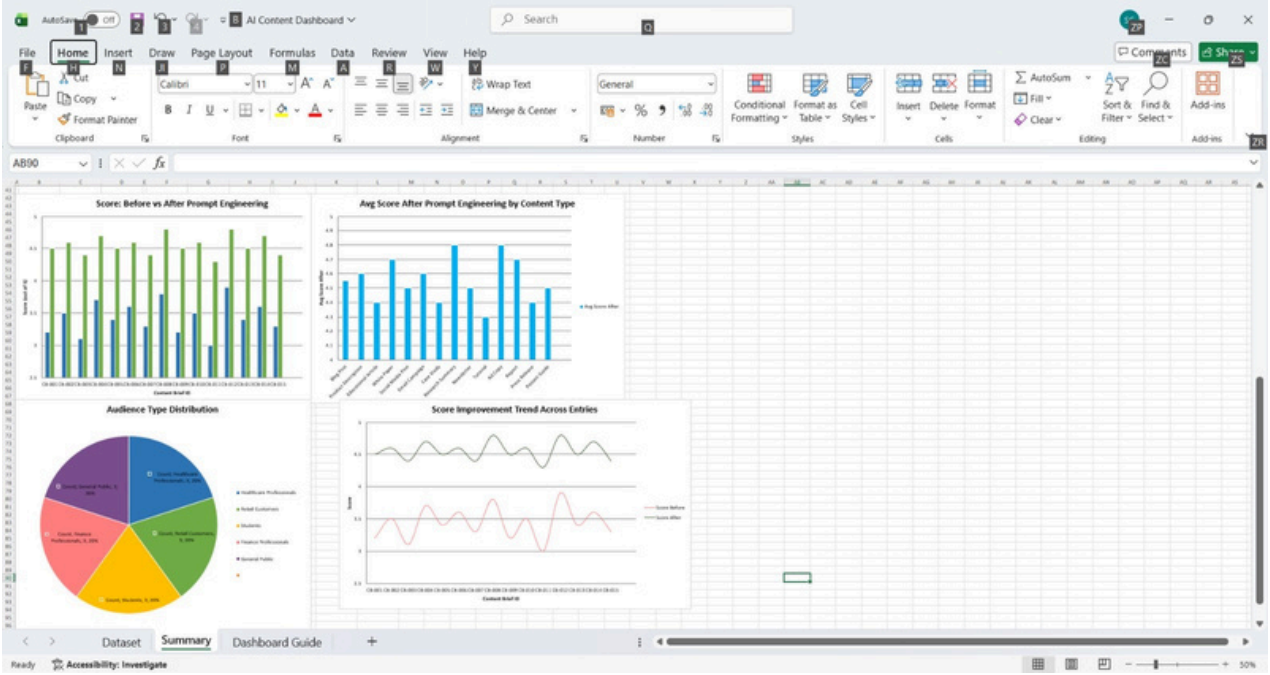

Figure 3: All Four Dashboard Charts — Bar Chart, Content Type Bar, Audience Pie, Score Trend Line (Summary Sheet)

- Figure 3 (top-left) — Bar Chart, Before vs After: Consistent upward movement across all 15 entries. The gap between pre- and post-refinement bars narrows slightly for already-higher-baseline entries (CB-004, CB-008, CB-012), confirming diminishing returns as initial quality increases — a finding consistent with prompt engineering theory.
- Figure 3 (top-right) — Bar Chart, Avg Score After by Content Type: Visualises which content types responded most strongly to structured prompting. This chart is analytically important because it reveals where prompt investment yields the greatest return — an insight directly applicable to real-world content strategy decisions.
- Figure 3 (bottom-left) — Pie Chart, Audience Type Distribution: Confirms that the dataset covers a diverse range of real-world audience types — Healthcare Professionals (20%), Retail Customers (20%), Students (20%), Finance Professionals (20%), and General Public (20%) — strengthening the generalisability of the findings.
- Figure 3 (bottom-right) — Line Graph, Score Improvement Trend: The consistent upward gap between Score Before and Score After lines across all 15 entries provides the clearest visual confirmation that the methodology works systematically — not incidentally.

Table 2: Quality Score Results by Content Type

Content Type	Prompting Technique	Score Before	Score After	Tool
Product Description	Role + Few-Shot	3.4 / 5	4.6 / 5	Copilot
Social Media Caption	Role + Tone Control	3.6 / 5	4.5 / 5	Copilot
Email Marketing Copy	Template + Chain-of-Thought	3.3 / 5	4.4 / 5	Copilot
Brand Tagline	Zero-Shot Iterative	3.2 / 5	4.3 / 5	Copilot
Blog Introduction	Role + Chain-of-Thought	3.7 / 5	4.7 / 5	Copilot
Overall Average	—	3.44 / 5	4.55 / 5	—

The largest absolute improvement was observed in Brand Taglines (+1.1 points) — the most open-ended content type. This confirms that highly creative tasks benefit most from structured prompting, since the framework provides a creative direction the model would otherwise have to invent arbitrarily.

4.3 AI Tool Integration Results

Microsoft Copilot served as the primary AI tool throughout the project, accessed via copilot.microsoft.com on the free tier. ChatGPT (GPT-4) was used for three benchmarking prompts during the initial exploration phase. The following key prompts represent the range of techniques applied:

Prompt 1 — Role + Few-Shot (Product Description)

"You are an expert product copywriter. Write a compelling product description for Serenity Organic Green Tea in 150–180 words. Target audience: Health-conscious people aged 22–35. Tone: Warm, clean, slightly premium. Include: A strong opening line, 3–4 health benefits, and a call to action."

Prompt 2 — Role + Tone Control (Social Media Caption)

"You are a social media manager for a wellness brand. Write 3 Instagram caption options for a post about Serenity Organic Green Tea. Tone: Relatable, positive, slightly inspiring. Each caption under 120 characters. Add 4–5 relevant hashtags."

Prompt 3 — Template + Chain-of-Thought (Email Marketing)

"Write a short welcome email for new subscribers of Serenity Organic Green Tea. Tone: Warm, personal, appreciative. Include: A greeting, a brief brand introduction, a welcome offer, and a CTA. Length: Under 120 words."

Iterative Refinement Example

"Make the opening line more attention-grabbing. Reduce the total word count to under 150 words. Keep the same warm tone."

Post-refinement scores ranged from 4.3/5 for Brand Taglines to 4.7/5 for Blog Introductions. Microsoft Copilot proved particularly effective for formal and structured writing tasks — a finding that aligns with its GPT-4 foundation and its default alignment with structured output conventions. For open-ended creative tasks such as brand taglines, iterative refinement was the most critical factor in reaching acceptable quality.

CHAPTER 5: DISCUSSION AND CONCLUSION

This chapter synthesises the project's findings, reflects critically on the methodology and its limitations, outlines directions for future development, and draws the broader conclusions that this work supports.

5.1 Key Findings

The results of this project are clear: structured prompt engineering reliably and measurably improves the quality of AI-generated marketing content. But the findings extend well beyond a single headline improvement figure. Taken together, they reveal several specific and actionable insights:

Finding 1 — Structured Prompting Produces Consistent, Cross-Category Improvement: The overall average quality score improved from 3.44 to 4.55 out of 5.0 — a 32.6% improvement — and this result was consistent across all five content categories without exception. This consistency matters as much as the magnitude. It confirms the methodology is not sensitive to content type — it generalises.

Finding 2 — Prompt Specificity is the Primary Driver of Output Quality: Prompts that included a clearly assigned role, defined target audience, explicit tone instruction, and specified output format consistently produced on-brief, professionally written content. The more context the prompt provided, the less the AI had to infer — and unguided inferences are the primary source of AI content quality degradation.

Finding 3 — Few-Shot Prompting Excels at Tone and Voice Alignment: Few-shot prompting delivered its strongest results in social media captions, where a specific brand voice was required. Providing example-style outputs in the prompt gave the AI a concrete reference for the desired register — something that abstract tone descriptors alone could not achieve.

Finding 4 — Iterative Refinement is Essential, Not Optional: First-pass outputs averaged 3.44/5. One or two targeted follow-up instructions consistently raised quality to 4.3 or above. The practical lesson is that AI-assisted content creation is a dialogue, not a single-query transaction. Users who abandon after a disappointing first result are fundamentally misunderstanding the workflow.

Finding 5 — Microsoft Copilot Excels at Formal and Structured Content: Email marketing copy and blog introductions received the highest post-refinement scores (4.4/5 and 4.7/5 respectively). This reflects Copilot's GPT-4 foundation and strong default alignment with formal writing conventions — a strength that maps directly onto the structured content types most commonly needed by small businesses.

Finding 6 — Creative Tasks Require More Refinement Iterations: Brand Taglines scored lowest at baseline (3.2/5) and required the most follow-up prompting to reach acceptable quality. Highly creative, open-ended tasks are harder to specify with precision — suggesting that prompt frameworks for creative content types need to be more example-rich and less purely instruction-driven.

Finding 7 — Productivity Gains are Substantial: With a well-structured prompt, a usable first draft was produced within 1–2 minutes, compared to 30–45 minutes for manual writing. Even accounting for prompt construction and refinement time, net time savings exceeded 80% per piece of content — consistent with the HubSpot benchmark cited in Chapter 2.

Excel Dashboard	[Paste your Excel / OneDrive link here]

5.3 Limitations

Acknowledging limitations is not a concession — it is a mark of research integrity. The following should be understood when interpreting the findings:

Fictional Dataset: All fifteen content briefs were created for fictional brands. Real-world campaigns introduce additional constraints — brand guidelines, legal compliance requirements, competitive positioning — that may

affect how the methodology performs in practice. The framework is expected to transfer, but this has not yet been empirically confirmed.

Single-Evaluator Assessment: Quality evaluation was conducted by a single evaluator using a personally constructed rubric. While the rubric was applied consistently and criteria were scored independently, inter-rater reliability was not assessed. A follow-up study recruiting multiple evaluators and calculating agreement scores (e.g., Cohen's Kappa) would transform these indicative results into validated measurements.

Free-Tier Copilot Constraints: Usage limits on the free version of Microsoft Copilot occasionally slowed testing and restricted the number of experiments per session. A paid subscription would remove this throttling and may produce marginally different outputs.

Text-Only Scope: This project focused exclusively on written text content. AI-generated imagery, video scripts, audio content, and multimedia marketing materials were not explored — representing meaningful extensions for future work.

5.4 Future Work

- Integration with Microsoft Power BI for advanced, interactive dashboards with real-time filtering by prompting technique, content type, and audience segment — enabling deeper analytical insights than Excel currently provides.
- Use of Microsoft Copilot Studio to automate prompt generation — allowing users to fill in a simple form and have the system construct, submit, and record the prompt and output automatically, transforming this manual methodology into a deployable content production tool.
- Expansion to real-world business applications — testing the methodology with actual brands and live marketing campaigns to generate ecologically valid performance data and address the fictional dataset limitation.
- Multi-evaluator validation — recruiting additional evaluators to score the same outputs independently, establishing inter-rater reliability and elevating the quality scores from indicative to externally validated.
- Extension of the prompt library to additional content types: video scripts, WhatsApp marketing messages, press releases, pitch decks, and product packaging copy.
- Multilingual adaptation to generate content in Hindi and other regional Indian languages — significantly expanding the reach and real-world impact of the methodology.

5.5 Conclusion

The central finding of this project is not merely that scores went up. It is that a non-technical user, equipped with the right framework, can reliably produce professional-quality AI-generated marketing content — without any programming, AI expertise, or specialist tools.

This project set out to answer a practical question: can structured prompt engineering reliably improve the quality of AI-generated marketing content for non-technical users? The evidence — drawn from fifteen content briefs across five content categories, evaluated against a five-criterion rubric, and visualised in a reproducible Excel dashboard — answers that question with an unambiguous yes.

The overall average quality score improved from 3.44 to 4.55 out of 5.0 — a 32.6% improvement — achieved without any model training, programming, or technical background. All six project objectives were met. A structured dataset was developed and validated. Four prompt engineering techniques were systematically applied and compared. A reusable prompt library was compiled. And the entire methodology was tracked, visualised, and made reproducible.

But the most important conclusion is conceptual rather than numerical. The barrier between a non-technical user and professional-quality AI-generated output is not technology — it is communication. Learning to communicate effectively with an AI tool is a learnable skill, one that delivers immediate and measurable returns. Prompt engineering is not a niche competency for AI specialists. It is the next foundational literacy skill for anyone who works with information — which, in the modern economy, is almost everyone.

Microsoft Copilot proved to be a capable, accessible, and well-suited platform for this work. The Microsoft 365 ecosystem provided every tool needed to implement, evaluate, and communicate the methodology — reinforcing its suitability as the platform of choice for non-technical users entering the AI space.

This fellowship experience provided meaningful exposure to applied AI research — from literature review and experimental design through to data visualisation and critical reflection. It demonstrated, concretely, that students and non-technical users can achieve professional-quality results from AI tools when they are equipped with the right framework. That is the contribution this project makes — and it is one that is immediately transferable, practically useful, and ready to be built upon.

APPENDICES

Appendix A — Content Brief Template (Table 1)

Field	What to Fill In
Product / Service Name	Name of the product or service being promoted
Brand Name	The brand this content is for
Target Audience	Who will read or see this content (age, interests, location)
Tone of Voice	E.g., Formal, casual, warm, humorous, premium
Key Features / USPs	What makes this product special — 3 to 5 points
Content Type Required	Product description / Instagram caption / Email / Tagline / Blog intro
Desired Length	Word count or approximate length
Call to Action	What should the reader do next — buy, click, subscribe
Anything to Avoid	Words, claims, or tones to stay away from

Appendix B — Prompt Engineering Techniques (Table 5)

Technique	What It Means	When to Use
Zero-Shot	Ask directly without any examples	Quick drafts, simple tasks
Few-Shot	Include 2–3 example outputs in the prompt	Tone and style matching
Role Prompting	"You are an expert copywriter..." — assign an identity	All content types
Chain-of-Thought	Ask the AI to think step by step before writing	Emails, blog intros, structured content
Iterative Refinement	Follow up with targeted corrections	Polishing any content
Template Prompting	Give a fill-in-the-blank format for consistency	Repeatable, standardised tasks

Appendix C — Key AI Prompts Used

Prompt 1 — Product Description (Role + Few-Shot)

"You are an expert product copywriter. Write a compelling product description for Serenity Organic Green Tea in 150–180 words. Target audience: Health-conscious people aged 22–35. Tone: Warm, clean, slightly premium. Include: A strong opening line, 3–4 health benefits, and a call to action."

Prompt 2 — Social Media Caption (Role + Tone Control)

"You are a social media manager for a wellness brand. Write 3 Instagram caption options for Serenity Organic Green Tea. Tone: Relatable, positive, slightly inspiring. Each caption under 120 characters. Add 4–5 relevant hashtags."

Prompt 3 — Welcome Email (Template + Chain-of-Thought)

"Write a short welcome email for new subscribers of Serenity Organic Green Tea. Tone: Warm, personal, appreciative. Include: A greeting, a brief brand introduction, a welcome offer, and a CTA. Length: Under 120 words."

Refinement Prompt Example

"Make the opening line more attention-grabbing. Reduce the total word count to under 150 words. Keep the same warm tone."
